Goals for This Check-In

Our goals for this check-in were to finish the services, complete an event-driven proof-of-concept, and move towards full frontend connection with the services.

Progress

Compared to the last check-in, where only the authentication service was connected to the frontend, we have completed all of the core services and connected the frontend.

We have also completed the event-sourcing proof-of-concept, which can be integrated across all services now that the core CRUD aspect of each of them has been completed.

Until the project presentation, we can work on event-sourcing and polishing the website.

Team Member	Contributions
Karine Davtyan	Implemented an event-driven architecture to separate user activity tracking from the core Book Service, utilizing a RabbitMQ message broker for asynchronous, fire-and-forget event handling. Configured Databricks Serverless SQL integration to securely process and persist user activity payloads via a standalone background consumer. Built event-triggering utility helpers within the book service to automatically log SearchExecuted and BookViewed actions without impacting API response times. This enables the backend to capture user behavior smoothly while laying the foundation for independent downstream consumers. Implemented performance optimizations using cachetools to cache heavy Databricks SQL aggregations and added CORS middleware to service entry points to support seamless frontend integration.
Angelina De Santis	Connected the EditProfilePage to the updated Authentication Service, which added account deletion, password changes, and profile picture management. Completed the Library Page feature

	for the frontend, complete with a LibraryProvider for managing global user library state, adding books to the library, sorting and filtering through the library, and changing the reading status of a book. Added a UserProvider to separate the handling of user specific services, like updating profile, from authentication services, like logging in. Started connecting the Discussion Service API to the frontend, allowing users to create posts for a certain book, view posts, and add replies. Added a search bar to the navbar.
Yawei Dong	Updated the library feature on both the backend and frontend. On the backend, added start_date and end_date fields to track user's reading progress and implemented validation to ensure end_date cannot be earlier than start_date. On the frontend, added a Grid View to the library page and implemented a view switch button, allowing users to switch seamlessly between List View and Grid View.
Manoj Ravichandran	Added Library Service frontend tests to verify key library behaviours and confirm that saved book data displays correctly across the user library pages. The Book Service frontend implementation was also completed by replacing mock-book usage with real Book Service API calls for the Discover page, the book details modal, and the full Book Page. This included loading real book descriptions, covers, ratings, and metadata, adding the View More flow, and connecting logged-in user actions such as reading status, favourites, and ratings through the Library service. Started writing tests for the frontend side of the book service.
Samin Sharif	Migrated the Discussion Service's database schema and business logic to match the self-contained, service-based structure (threads, replies, tags, and likes) each with proper cascade rules. Fixed authentication gaps where user IDs were trusted from the request body (letting anyone post or like as another user) by resolving them server-side from a verified token instead. Added full edit/delete support for threads and replies with author-only ownership checks, plus a spoiler flag so posts can be hidden by default. Redesigned tags to auto-create from free text instead of requiring pre-existing IDs, and fixed an N+1 query issue so thread

	lists can show like/reply counts without a query per thread. All CRUD endpoints have been added for the discussion service.
Owen Zhu	Added analytics aggregation for discussion forum to return thread and reply likes, created service for returning list of popular threads based on likes and boosted by recency. Added test files to ensure proper table injections into Supabase for liking and nested replies.
